

Multidimensional Evaluation and Attribution Analysis of Food Inflation Forecast in Australia. (a) Overview of the total cycle prediction and fitting, (b) Multi-step Short-Term Forecast Comparison Chart, (c) Details of Prediction Performance in Extreme Crisis Periods, (d) Pearson correlation analysis of macroeconomic drivers, (e) SHAP-based explanation of feature contributions for a specific prediction instance.

Extreme weather causes a high degree of uncertainty, and the rising supply of labor costs is a dual-core driving force of Australian food inflation. As a country vulnerable to El Niño and La Niña events, Australia has experienced frequent sharp changes in drought and flood that have directly hit its core agricultural belt of Queensland and Victoria, causing multiple interruptions in the harvest cycle of fresh fruits and vegetables and sharp jumps in prices due to sharp declines in production. Simultaneously, the agriculture, food processing, and logistics industries have been facing a serious labor shortage for a long time in the post-pandemic era, and wage increases in picking and distribution have been forced to be passed on to terminals through the supply chain. In addition, high energy prices drive the increase in the cost of fertilizers and pesticides, and the highly concentrated retail structure of the domestic supermarket industry makes the price transmission very fast when the cost rises, and the retail price decreases slowly when the cost falls, forming a significant downward stickiness.
